1. Interpreter and Compiler
Interpreter
An interpreter is a translator that executes a program one statement at a time. It translates and executes the code during runtime.

Advantages:
 Easy to debug errors.
 No separate compilation step is required.
 Suitable for interactive programming.
Example: Python is commonly described as an interpreted language.
Compiler
A compiler translates the entire source program into machine code or another target form before execution.

Advantages:
 Compiled programs generally execute faster.
 Many errors can be detected before execution.
 The compiled output can be run without recompiling every time, provided the target environment is compatible.

2. Object-Oriented Programming (OOP) Approach
Object-Oriented Programming (OOP) is a programming approach that organizes a program using classes and objects. It combines data and the methods that operate on that data.
Main concepts of OOP
1. Class: A blueprint used to create objects.
2. Object: An instance of a class.
3. Encapsulation: Combining data and methods into a single unit and controlling access to the data.
4. Inheritance: Creating a new class from an existing class.
5. Polymorphism: Allowing the same interface or method name to behave differently in different contexts.
6. Abstraction: Hiding implementation details and exposing essential features.
